METHODS AND RESOURCES

Recording animal-view videos of the natural world using a novel camera system and software package

Abstract

Plants, animals, and fungi display a rich tapestry of colors. Animals, in particular, use colors in dynamic displays performed in spatially complex environments. Although current approaches for studying colors are objective and repeatable, they miss the temporal variation of color signals entirely. Here, we introduce hardware and software that provide ecologists and filmmakers the ability to accurately record animal-perceived colors in motion. Specifically, our Python codes transform photos or videos into perceptible units (quantum catches) for animals of known photoreceptor sensitivity. The plans and codes necessary for end-users to capture animal-view videos are all open source and publicly available to encourage continual community development. The camera system and the associated software package will allow ecologists to investigate how animals use colors in dynamic behavioral displays, the ways natural illumination alters perceived colors, and other questions that remained unaddressed until now due to a lack of suitable tools. Finally, it provides scientists and filmmakers with a new, empirically grounded approach for depicting the perceptual worlds of nonhuman animals.

Who Is the Observer?

Every camera records colors differently.

Color Perception

Perception of one color is influenced by the other colors around it: "simultaneous color contrast".

Color Perception

Color is only
meaningful under
a given light.

#thedress

Color Perception

Color is only
meaningful under
a given light.

#thedress

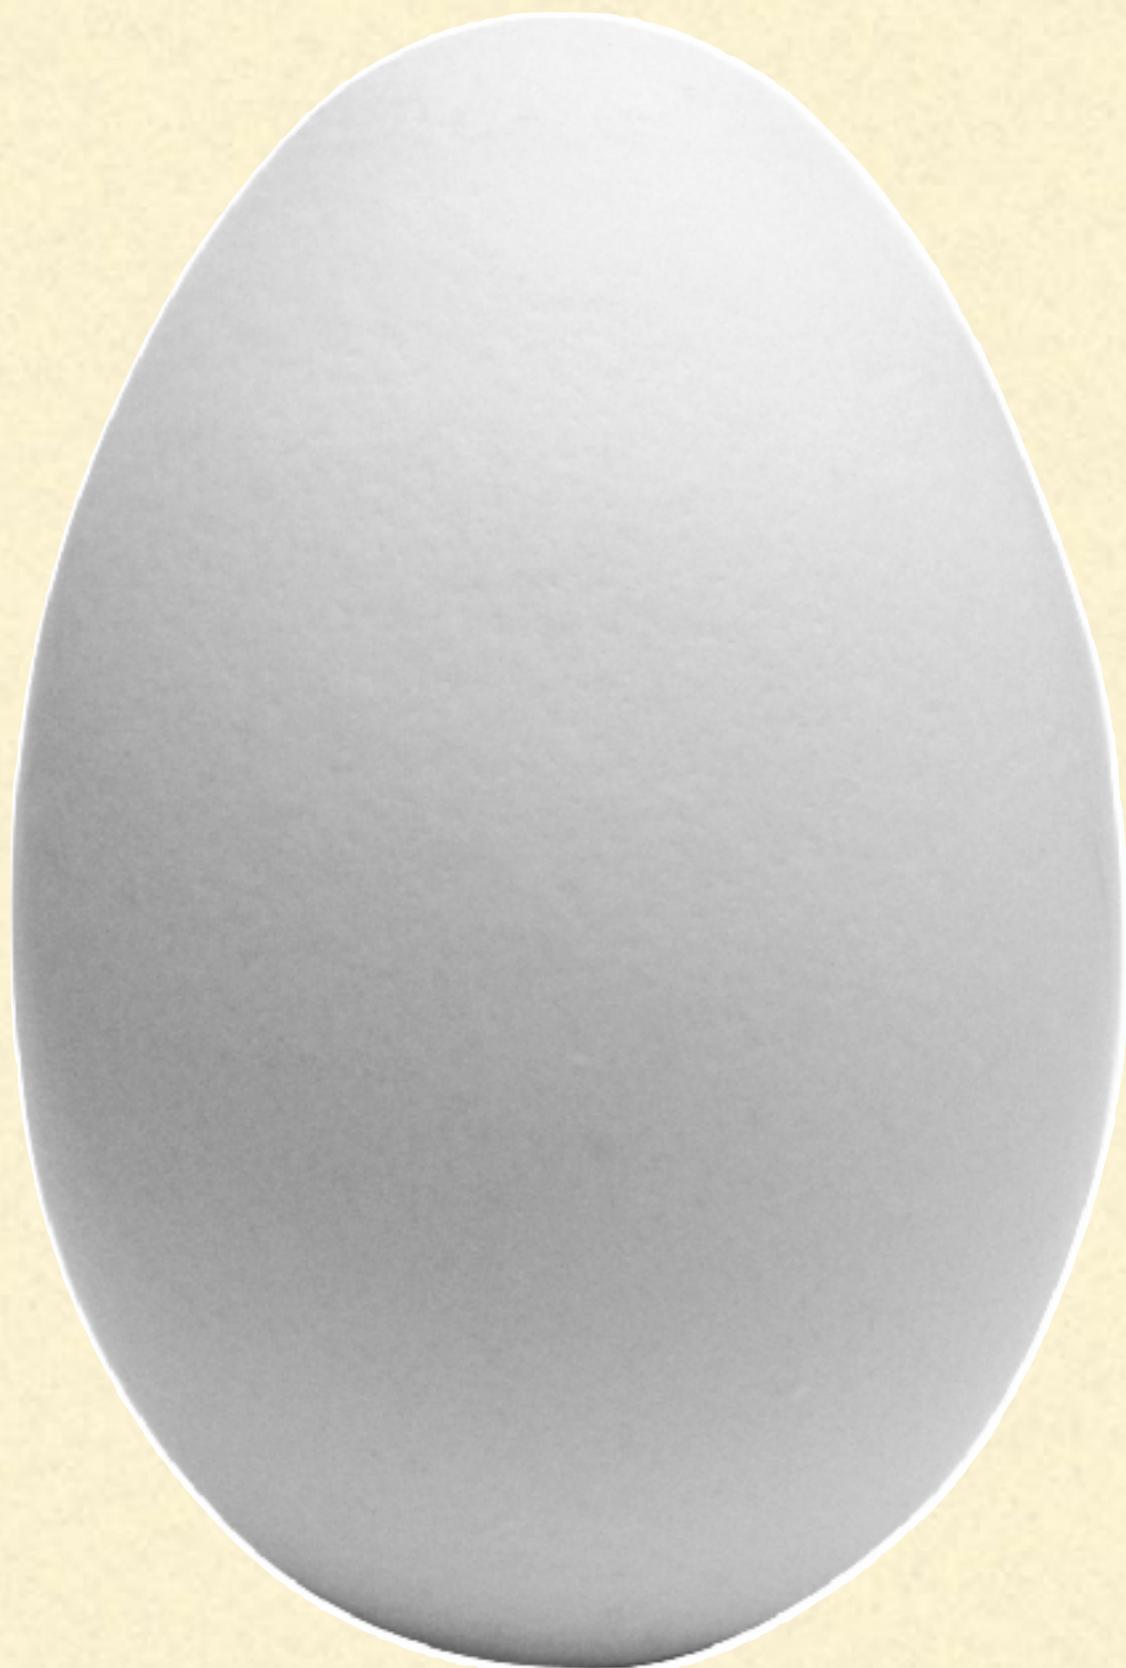

Color Constancy

Color constancy is the human visual system's ability to perceive colors consistently under varying light conditions.

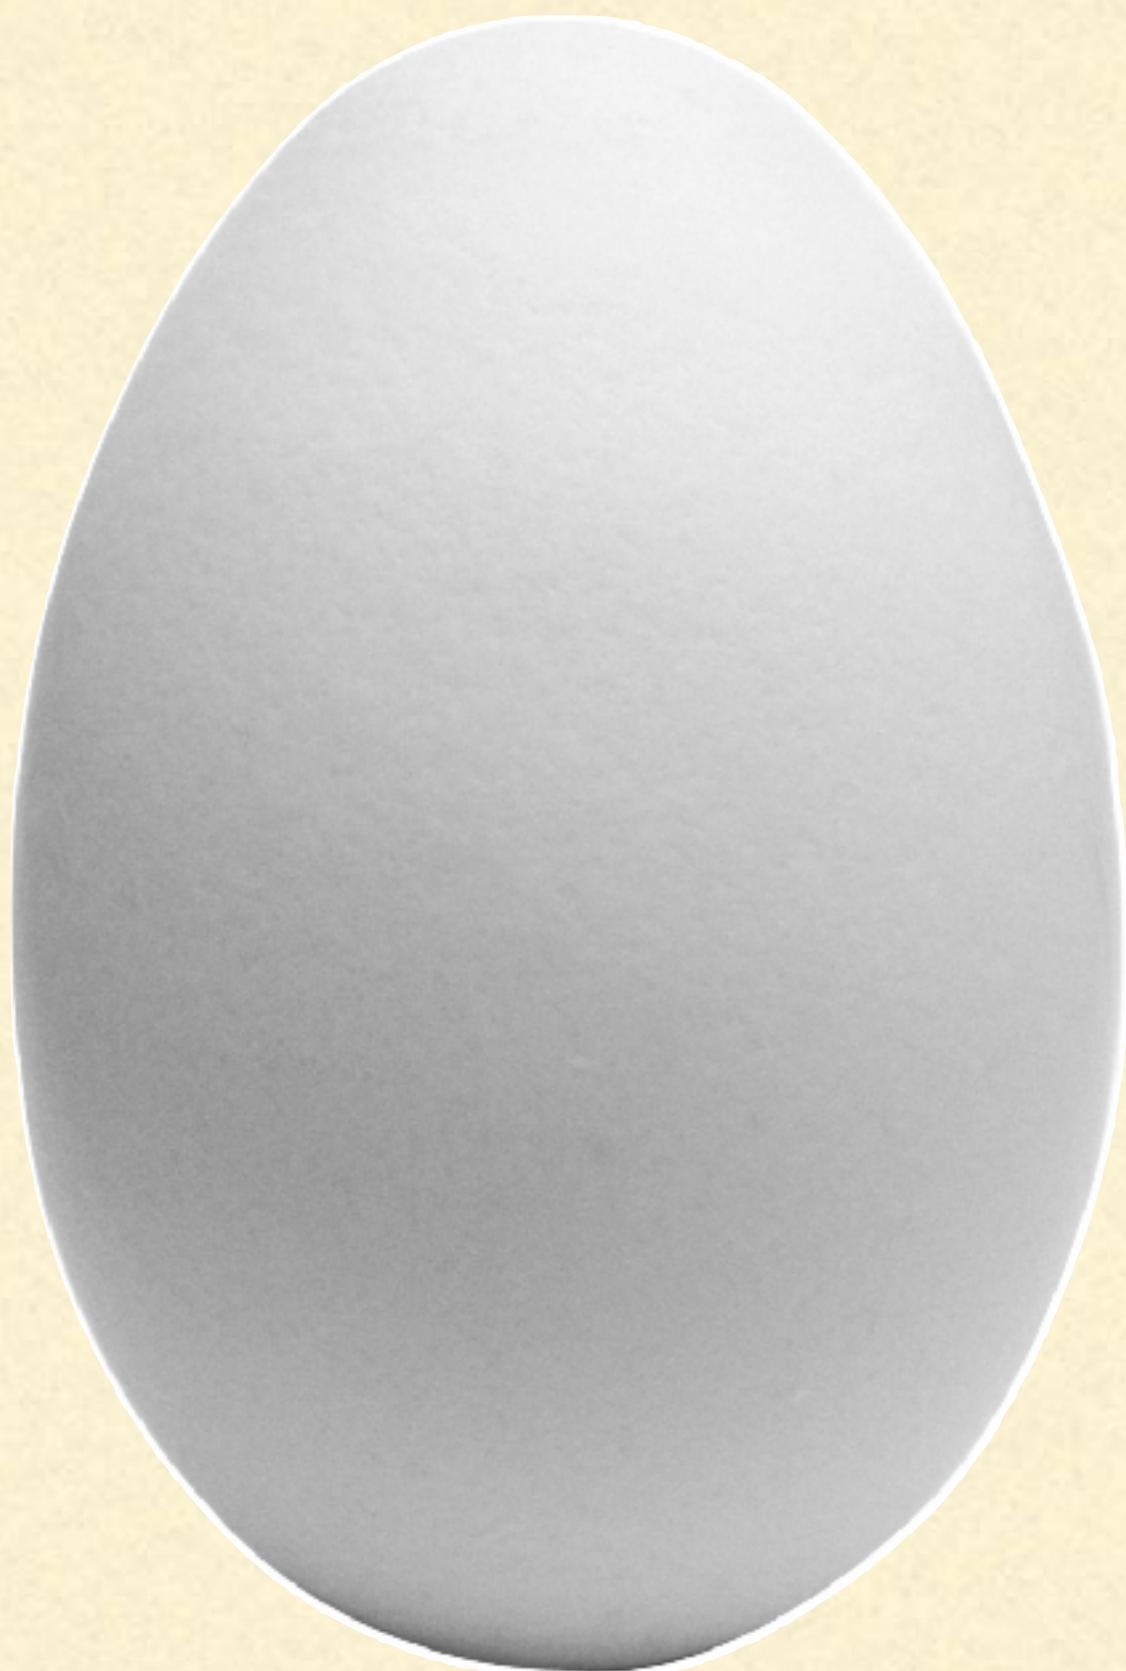

Color Constancy

Color constancy is the human visual system's ability to perceive colors consistently under varying light conditions.

HOW CAN WE MEASURE

A SUBJECTIVE QUANTITY

OBJECTIVELY?

COLORIMETRY

Is the science of measuring colors.

Where in life (and research) does it come handy to measure colors?

Color Theory

- ▶ Colorimetry
- ▶ Uniform/expanded color spaces
- ▶ Color gamuts
- ▶ Models of color perception
- ▶ Mathematical models of color
- ▶ Color appearance models

The mere presence of a smartphone reduces basal attentional performance

Jeanette Skowronek[✉], Andreas Seifert & Sven Lindberg

The smartphone has become an indispensable part of everyday life. It enables endless possibilities and offers persistent access to a multiplicity of entertainment, information, and social contacts. The development towards a greater use and a persistent presence of the smartphone does not only lead to advantages, but also raises potential for negative consequences and a negative influence on attention. In this research, the hypothesis of the mere smartphone presence leading to cognitive costs and a lower attention is being tested. The smartphone may use limited cognitive resources and consequently lead to a lower cognitive performance. To investigate this hypothesis, participants aged 20–34 perform a concentration and attention test in the presence and absence of a smartphone. The results of the conducted experiment imply that the mere presence of a smartphone results in lower cognitive performance, which supports the hypothesis of the smartphone presence using limited cognitive resources. The study as well as the subsequent results and the resulting practical implications are presented and discussed in this paper.
